To prove that this circuit arrangement made the detector a potential operated device, four of these detector circuits, each with its separate indicating instrument, were arranged so that they could be simultaneously in connection with an antenna circuit tuned to distant signals. It was found that in no case was the signal intensity in the first set decreased by connecting on one or all of the other three. Moreover the signals in all four receivers were approximately equal. The slight inequalities were due to difference in sensitiveness of the separate detectors. The effect on a single indicator could be proportionally increased by connecting it to the secondary winding of a transformer, having separate primaries which were connected to the separate detectors. Theoretically...
